Homework 7

Benjamin Noland

- 1. (Cryer & Chan, Exercise 9.1)
- 2. (Cryer & Chan, Exercise 9.2)
- 3. The following simulates an MA(2) process with $\theta_1 = 1, \theta_2 = -0.6$, and $\mu = 100$:

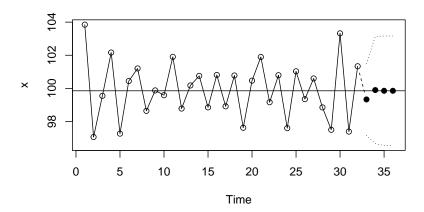

```
set.seed(1432756)
series <- arima.sim(model = list(ma = c(-1, 0.6)), n = 36) + 100</pre>
```

a. The following uses the first 32 observations of the process to compute maximum likelihood estimates of θ_1 , θ_2 , and μ :

```
# Set aside the first 32 values for computing forecasts.
training <- window(series, end = 32)</pre>
model <- arima(training, order = c(0, 0, 2), method = "ML")
model
##
## Call:
## arima(x = training, order = c(0, 0, 2), method = "ML")
##
## Coefficients:
##
            ma1
                         intercept
                   ma2
##
         -1.097
                 0.326
                             99.85
## s.e.
          0.154
                 0.168
                              0.05
##
## sigma^2 estimated as 1.23: log likelihood = -49.5,
                                                          aic = 105
```

b. The following plots the time series along with the 4 forecasted values (the solid black points), pointwise 95% prediction limits, and a solid horizontal line indicating the estimated value of μ :

```
res <- plot(model, n.ahead = 4, pch = 19)
abline(h = coef(model)[["intercept"]])</pre>
```

The following are the four predicted values:

```
preds <- res$pred
preds

## Time Series:
## Start = 33
## End = 36
## Frequency = 1
## [1] 99.3 99.9 99.9 99.9</pre>
```

- c. The forecasts at lead times 3 and 4 are *very* close to the estimated value of μ , and therefore lie almost along the horizontal line in the plot in part (b).
- d. The true values are as follows:

```
truth <- window(series, start = 33)
truth

## Time Series:
## Start = 33
## End = 36
## Frequency = 1
## [1] 98.2 101.6 97.7 103.1</pre>
```

We therefore have the following pointwise deviations:

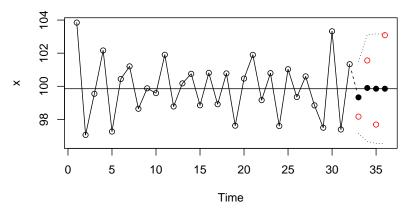

```
as.numeric(preds) - as.numeric(truth)
```

```
## [1] 1.16 -1.66 2.17 -3.24
```

Thus the model overestimates the true values at lead times 1 and 3, and underestimates the true values at lead times 2 and 4.

e. The following is the same plot as in part (b), but with the true values plotted as red circles. Each of the actual values appears to lie within its corresponding 95% prediction interval.

```
plot(model, n.ahead = 4, pch = 19)
points(y = truth, x = time(truth), col = 2)
abline(h = coef(model)[["intercept"]])
```

f. The following code simulates the same process as above 500 times and computes the fraction of times the forecast limits cover each of the true values.

```
set.seed(1432756)
N < -500
count <- 0
for (i in 1:N) {
  # Simulate the process and fit a model on the training subset.
  series \leftarrow arima.sim(model = list(ma = c(-1, 0.6)), n = 36) + 100
  training <- window(series, end = 32)</pre>
  model <- arima(training, order = c(0, 0, 2), method = "ML")
  # Compute the forecasts and get the upper/lower prediction limits.
  res <- plot(model, n.ahead = 4, Plot = FALSE)
  upper <- res$upi
  lower <- res$lpi</pre>
  # Do all the forecasts lie within their respective prediction intervals?
  truth <- window(series, start = 33)</pre>
  success <- all(truth >= lower & truth <= upper)
  count <- count + success</pre>
}
count / N
```

Thus the forecast limits cover each of the true values approximately 78.4% of the time.

4. (Cryer & Chan, Exercise 9.23)

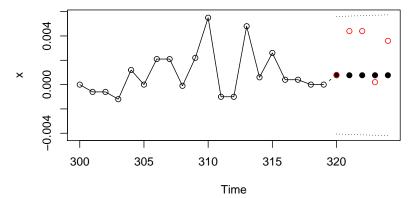

[1] 0.784

a. The following code fits an IMA(1, 1) model to all but the last five values of the time series:

```
data(robot)
training <- window(robot, end = length(robot) - 5)</pre>
model \leftarrow arima(training, order = c(0, 1, 1))
model
##
## Call:
## arima(x = training, order = c(0, 1, 1))
##
## Coefficients:
##
             ma1
##
          -0.878
## s.e.
           0.042
##
## sigma^2 estimated as 6.07e-06: log likelihood = 1458, aic = -2914
Next, we use this model to forecast the final five observations in the time series,
which were left out when fitting the model:
res <- plot(model, n.ahead = 5, Plot = FALSE)
The forecasts are
as.numeric(res$pred)
## [1] 0.000769 0.000769 0.000769 0.000769
and the upper and lower prediction limits are
as.numeric(res$upi)
## [1] 0.00560 0.00563 0.00567 0.00571 0.00574
and
as.numeric(res$lpi)
## [1] -0.00406 -0.00410 -0.00413 -0.00417 -0.00420
respectively. Notice that each of the forecasts are the same, as should be the case
for an IMA(1, 1) model with no constant term (as is the case here).
```

b. The following is a plot of the time series, along with the forecasts (solid black points) and their associated 95% prediction limits, as well as the associated true values (red circles). The plot is restricted to the end of the time series for easy visualization.

```
plot(model, n.ahead = 5, n1 = 300, pch = 19)
truth <- window(robot, start = length(robot) - 5 + 1)
points(y = truth, x = time(truth), col = 2)</pre>
```

From this plot we see that each of the true values lies within the prediction limits for the corresponding forecast. As mentioned in part (a), all of the forecasted values are the same, and this is shown on the plot.

c.
